**Resumo**

This paper investigates if the equity stake, along hedge funds, generates value for target companies in less sprayed markets, such as the Brazilian one. In a sample with 324 public companies that belonged to the Anbima Hedge Fund Index (IHFA) between 2007 and 2016, we found a positive and significant relation between the equity stake of hedge funds and the value generation in invested companies, despite the Brazilian market being more concentrated. Our results suggest that the hedge fund activism is increasing in Brazil, with funds' managers influencing firms' decisions and corporate governance mechanisms.

## HEDGE FUNDS AND THE MARKET RETURN

### ABSTRACT

This paper investigates if the equity stake, along hedge funds, generates value for target companies in less sprayed markets, such as the Brazilian one. In a sample with 324 public companies that belonged to the Anbima Hedge Fund Index (IHFA) between 2007 and 2016, we found a positive and significant relation between the equity stake of hedge funds and the value generation in invested companies, despite the Brazilian market being more concentrated. Our results suggest that the hedge fund activism is increasing in Brazil, with funds' managers influencing firms' decisions and corporate governance mechanisms.

**Keywords:** Hedge funds; Market Return; Target Companies.

### 1 INTRODUCTION

The heritage managed by the regulated investment funds' industry worldwide has doubled in the past decade, surpassing the \$ 49 trillion dollars' mark of total net assets at year-end 2017 (ICI, 2018). The U.S owns almost half of these resources, followed by Europe and Asia. The increasing interest in these funds is not a trend restricted to developed countries. Emerging markets hedge funds have been improving their activities in short selling, derivatives instruments, arbitrage and activist strategies to deliver higher diversification benefits to institutional and small investors (Eling & Faust, 2010; Chen, 2011; Abugri & Dutta, 2009).

Prior research have been exploiting emerging markets as one among a big number of investment strategies in hedge funds, focusing on funds' performance measurements, but not in how those hedge funds can add value to the invested companies (Fung & Hsieh, 2001; Capocci & Hubner, 2004; Ackermann, McEnally, & Ravenscraft, 1999). By their nature, emerging markets exhibit economic and politic risks, information asymmetry costs, and stock volatility; in contrast, they provide growth opportunities (Al-Deehani & Moosa, 2006; De Santi & Imrohoroglu. 1997). In this sense, emerging markets are targets to hedge funds managers, who tend to acquire participation in less profitable and weakly governed firms (Clifford, 2008; Brav, Jiang, Partnoy, & Thomas, 2008; Greenwood & Schor, 2009; Gantchev, 2013; Bebchuk, Brav & Jiang, 2015).

On the other hand, in developed markets, where the majority of stocks are not held by few investors and insider information occur less frequently (Ball, Kothari & Robin, 2000), main studies document the existence of a positive relation between hedge funds and value creation in invested firms (Clifford, 2008; Brav et al., 2008; Becht, Franks, Grant, & Wagner, 2017). For instance, Bessler, Drobetz e Holler (2015) documented that hedge funds enhanced the stock value in German companies, both short and long term. Recently, Becht et al. (2017) found evidences in 23 developed countries that hedge funds activism generates an average positive alpha in big companies.

Then, we ask if less sprayed markets in emerging economies mimic this phenomenon. This paper investigates if the equity stake alongside hedge funds generates value to invested firms (hereafter, target companies) in the Brazilian market. We use Brazil as an experiment due to its increasing position in global and domestic investment portfolios based on emerging markets. The Brazilian domestic funds industry has grown 17.3% in 2016, in net assets, in comparison to 2015, and reached the almost 60% of the nominal GDP of 2016, despite the high tax burden on capital gains (Anbima, 2017)<sup>1</sup>.

---

<sup>1</sup> The Brazilian fund market is the tenth largest in the world, with approximately 3% of the global heritage, an average growth of 16.6% per year of net assets, and more than 15,000 funds under management (Anbima, 2017).

In the U.S. market, hedge funds' target firms experience improvements in their operating performance, CEO turnover and payout policies, under funds managers' activism (Brav et al., 2008). It reveals that hedge funds are able to monitor and intervene on corporate governance in invested companies, increasing value for the shareholders. In general, fund managers around the world have a substantial piece of their compensation from incentive fees: they receive bonus only when get a positive portfolio return, and after making up all previous losses (Fung & Hsieh, 1997). Doing this way, hedge funds activism can generate value to investors, reducing information asymmetry costs to them.

We capture the hedge fund effect on invested companies in terms of: (i) how much the firms' market capitalization is maintained by hedge funds and its percentage change between  $t$  and  $t-1$ ; (ii) how many funds invest in a determined company each period and its percentage change between  $t$  and  $t-1$ . We defined target firm value creation using two proxies: abnormal return and effective stock return.

In a sample with 324 Brazilian companies listed in São Paulo Stock Market (B3) that are actively participating in the Anbima Hedge Fund Index (IHFA), between 2007 and 2016, we found that the equity stake of hedge funds generates value in Brazilian invested companies, despite the market being more concentrated. This effect is conditional positive to the growth of hedge funds participation in emerging market firms, and it is conditional negative to the participation of hedge funds solely. The negative effect endorse the argument that funds look to the emerging market searching undervalued firms (Brav et al., 2008). To derive our results, we performed linear regressions with funds fixed effects and a set of funds characteristics acting as controls.

This study contributes to academic and practical discussion of the addressed theme, since it shows evidence that investor activism is growing in emerging markets, despite all inefficiency caused by market concentration. In addition, our results imply that hedge funds signal, somehow, what kind of undervalued firms represent a good alternative of investment in emerging markets.

The remainder of the paper is organized as follows. Section 2 provides a background on investment funds and hedge portfolios. Section 3 describes the research design and the sample, while Section 4 focuses on our results and robustness checks. Section 5 concludes.

## 2 BACKGROUND

### 2.1 Hedge Funds Equity Stake

Although hedge funds may gather significant participation in target companies (Bessler, Drobetz & Holler, 2015), these participations would not influence managers' investment decisions if there is no bargain power. Bradley and Chen (2011) and Tirole (2006) suggest that the bargain power in this context depends on the investors' ability of convincing other shareholders about their proposals' accomplishments. According to Becht et al., (2017), hedge funds may accumulate relevant equity stakes, and the effects of it are particularly strong if the institutional investor has a good reputation, being able to identify companies with growth potential.

The Brazilian Securities Commission CVM instruction number 358, of January 3rd 2002, is responsible for promoting information about acquisition and disposal of relevant equity stakes. This rule establishes that relevant negotiations, when upper than 5% of the heritage, must be followed by bulletins informing the company about the purpose of the participation and, when in case, declaring that the business does not want to change structure in control or management in ownership.

It is not different around the world. All 23 countries analyzed by Becht et al. (2017), require that shareholders announce it when participations reach a minimum limit. In most countries, this limit is 5% of the equity. Germany, Italy, Switzerland and the UK have limits

lower than 2% or 3%, while Canada has a limit upper than 10%. The United States requires more restrict guidelines. American investors that have specific plans able to affect significantly the company, or its management in the future, are called active block investors and forced to disclose it (Bessler et al., 2015; Clifford, 2008).

Hedge funds have important advantages in comparison to other types of institutional investors. Hedge funds managers have more incentives to generate positive returns than their counterparties, since hedge funds charge a performance fee, based on the fund observed profitability. Those funds are also able to use leverage strategies and derivatives that are forbidden for many institutional investors (Brav et al., 2008).

These mechanisms, according to Shleifer and Vishny (1997), ensure hedge funds against anticipated withdrawals and reduce agency problems between fund managers and investors, signaling that they can participate of capital restructures processes in the long run (Brav et al., 2008). However, hedge funds managers have more incentives to engage in riskier activities with high leverage strategies, sometimes compromising the target companies performance (Klein & Zur, 2011).

Bessler, Drobetz and Holler (2015) also relate that agreements on the payment of hedge funds managers are directly related to their performance, what generates strong incentives to find profitable investments and actively monitor target companies. Besides it, funds regulations can predict specific deadlines for redemption or even blockages. In this sense, Brav et al. (2008) suggest that limits on trading the invested capital enables hedge funds apply their resources in less profitable assets in the short run, but with a potential future effect on valuation.

Brav et al. (2008) reveal that hedge funds monitoring and its interventions on corporate governance in target companies increase value for the shareholder. Using data collected between the years of 2001 and 2006, Brav et al. (2008) found out that the most active role (activism) of American hedge funds propose strategic, operational and financial solutions. Results point out success in two thirds of the cases and abnormal return of stocks after the announcement of approximately 7% of activism.

Klein and Zur (2009) also provide evidence of rising prices in stocks from target companies in the short and long run. Greenwood and Schor (2009) suggest that hedge funds get a specialization in identifying badly managed target companies, searching for directing and grouping them. Clifford (2008) reports that companies that are directed by asset funds generate abnormal positive returns and improvements on the performance measured by Return on Asset (ROA), in comparison to the group of companies directed by the same hedge funds for liability purposes.

Gillan and Starks (2007) shows that activism of institutional investors is not a new phenomenon. On the mid-twentieth century, American financial institutions, such as insurance companies, investment funds and banks were asset participants in corporative governance, acting in corporate services and taking important roles in the strategic direction of the company. Decades ago, Smith (1996) emphasized that shareholders' activism is highly successful in changing the governance structure and results in an statistically relevant increase on shareholders' wealth.

Given this background, we hypothesize that hedge funds can generate value for the shareholders also in less sprayed markets, with undervalued firms' portfolios.

**H1: The overall equity stake of hedge funds generates value for target companies in less sprayed markets, like the Brazilian one.**

## 2.2 Brazilian Investment Funds

The CVM instruction number 555, of December 17<sup>th</sup> 2014, defined the classification of investment funds in fixed income, exchange or multimarket. About 2015, the Brazilian

Association of Financial and Capital Markets Entities (Anbima), in order to increase transparency and allow comparison between funds, announced a booklet named New Investment Funds Classification. This document seeks for detailing each one of the new classifications, the benefits of this market change and the decision-making process steps.

Among the classification defined in the CVM instruction number 555, the category that is more similar to a traditional hedge fund portfolio is the multimarket funds (Joaquim, Passarelli & Leite Moura, 2011; Malaquias & Eid, 2014). It is an investment category that involves many risk factors, without the commitment of concentrating in any factor in particular (Anbima, 2017), besides other characteristics such as the adoption of leveraged positions, derivatives operations and performance rate payment (Malaquias & Eid, 2013).

The New Classification of Investment Funds (Anbima, 2017) defines three levels. Tables 1 and 2 show it. The first level highlights the asset classes that follows the adopted classification by CVM in instruction number 555. The second level identifies the management type and the risks associated to that management. The third level details the fund strategies.

Table 1  
**New Funds Classification – ANBIMA**

This chart presents Level 1 – Asset Class: the classification of investment funds, according to the CVM instruction number 555, of December 17th 2014; Level 2 – Types of Management and Risks: the types of management and the associated risks to each one; Level 3 – Strategies: details specified strategies that funds may adopt.

Regulation (CVM-Instruction number 555/14)	Autoregulation (ANBIMA)	
Level 1	Level 2	Level 3
Asset Class	Types of Management and Risks	Strategies
Fixed Income Stocks Multimarkets Foreign Exchange	Indexed Assets Foreign Investment	According to the Strategy

Source: CVM instruction number 555 adapted

Table 2  
**Multimarket Funds Classification**

This chart presents categories and subcategories of multimarket funds, according to the CVM instruction number 555, of December 17th 2014; the categories where types of management and associated risks are defined; and the subcategory that details specific strategies that these funds may adopt.

Asset Class	Category	Subcategory
Multimarket	Allocation	Balanced
		Dynamic
	Strategy	Macro
		Trading
		Neutral <i>Long and Short</i>
		Directional <i>Long and Short</i>
		Interest rate and Currencies
		Free
		Protected Capital
	Specific Strategy	
	Foreign Investment	Foreign Investment

Source: CVM instruction number 555 adapted

In addition, The Anbima Hedge Funds Index (IHFA) was created in 2008 to intensify the monitoring activities of this segment. This index value is a reflection of the evolution of a hypothetical application of quotas in baskets of funds selected according to specific criteria.

Funds that are part of the multimarket class and with more than one year of operation belong to the IFHA. Besides that, the methodology adopted by Anbima (2017) excluded funds:

- Constituted by the closed condominium form, exclusive;
- That do not charge a performance tax;
- Which average number of holders in the quarter that precedes the rebalancing date of the index is lower than ten;
- That do not disclose the quota value updated daily;
- In investment funds quotas that do not have, at least, 95% of its equity invested in a single investment fund;
- Which equity average in the quarter that precedes the rebalancing date of the index is inferior to the median value of the sample;
- Which volatility annualized – taking as a basis the variability of observed daily returns – in the quarter that precedes the rebalancing date of the index is inferior to the first quarter of the sample.

The theoretical portfolio of IHFA has a quarterly balancing and validity to periods from January to March, April to June, July to September and October to December, and it is calculated from provided data by CVM.

### 3 DATA AND METHODOLOGY

#### 3.1 Sample

In order to assess the relation between the joint equity stake of Brazilian hedge funds and the generation of value for target companies in terms of stocks return, we used data of 324 companies, listed in São Paulo Stock Market (B3) that had participation in multimarket funds from the IHFA index. Overall, 555 funds are part of the IHFA index since the beginning of the series, that started on the last quarter of 2007, being 499 investment funds (FI) and 56 investment funds in investment funds quota (FIFIC).

The selection of the samples used in this study considers funds that are part of the IHFA index (data requested by Anbima) and information collected in Economática and Quantum Axis databanks for the period of 2007 to 2016. In Economática, there were informations as: stock return, profitability, beta, volatility, debt and market value – reference to stocks listed in market that have shareholders as Brazilian hedge funds.

The companies selected are listed in 20 sectors according to the classification of the software Economática@ and were categorized in Agriculture, Livestock and Fishing; Food and Beverage; Commerce; Construction; Electronics; Electric Energy; Finance and Insurance; Industrial Machines; Mining; Non-Metallic Minerals; Paper and Cellulose; Oil and Gas; Chemistry; Steel and Metallurgy; Software and Data; Telecommunications; Textile; Transport and Vehicles.

In Quantum Axis databank, we extracted information about the composition of portfolios in funds, such as stocks implementations and stocks loans. By the composition of portfolios, it is possible to identify sectors, companies that the investment fund uses their resources, the number of stocks in portfolios or borrowed at the end of each period and the financial volume used in each strategy. The Table below details the number of hedge funds in each economic sector from 2007 to 2016, period of analysis in this research.

Table 3

**Total Amount and Annual Average of Hedge Funds Per Economic Sector**

This table presents the allocation in variable income of resources in investment funds classified as multimarket, inserted in IHFA – Anbima index per economic sector (categories defined by the software Economática).

Economic Sector (Economática)	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016
Commerce	47	68	66	43	53	72	59	61	42	22

Construction	47	70	113	76	52	115	51	53	23	12

Font: Elaborated by the author

As it can be seen in Table 3, hedge funds were more presented in the stock market between 2007 and 2009, where a raise occurred in the participation of electric, paper and cellulose, and oil and gas sectors. However, right after this period, it can be seen the reduction of hedge funds performance, which can be related in the global crisis of 2008 and political-economic instability experienced in Brazil since 2015.

Between 2015 and 2016, the Brazilian economic indicators show a big economic recession, with inflation bigger than the maximum bandwidth of the target of 6.5% established by the National Monetary Council (CMN) and basic interest fees reaching 14.25% per year. With the additional of political instability to these factors, there was a decrease in foreign investment and the capital market outflow, that raised the concentration of investments in fixed income securities. These factors may justify, then, the sublease in Stock Market by multimarket funds.

### 3.2 Research Design

We based on Bessler, Drobetz and Holler (2015) to build our research design and verify if the joint participation of hedge funds generates value for target companies in less sprayed markets, like the Brazilian one. The equation 1 intends to capture this effect.

$$y_{it} = \beta_0 + \beta_1 PartHF_{it} + \beta_2 NHF_{it} + \beta_3 \Delta PartHF_{it} + \beta_4 \Delta NHF_{it} + \beta_5 EHF_{it} + \beta_6 SHF_{it} + \sum_{k=1}^N \beta_k C_{it} + \omega_i + \theta_t + \varepsilon_{it} \quad (1)$$

The dependent variable  $y_{it}$  is defined using three proxies for shareholder value:  $RA_{it}$  is the abnormal return;  $RE_{it}$  is the actual stock return; and  $Vol_{it}$  is the stock volatility.  $C_{it}$  is the vector of control variables. The table below presents the variables description. Further information about the returns variables definitions are in equations 2 and 3.

Table 4

#### Variables Description

Variables	Description	Calculation Formula	Period
RA	Abnormal Stock Return	Further explanations in item 3.2.1 and equation 4	Monthly

RE	Effective Stock Return	Ratio between the stock price in period t and stock price in period t-1	Monthly
Vol	Stock Volatility	Standard deviation of company return i in period t	Monthly
PartHF	Participation of hedge funds in percentage	How much, in percentual terms of market value of company i in period t, is owned jointly by hedge funds;	Monthly
NHF	Number of hedge funds investing in each target firm	Quantity of funds that invest in a determined company i at the end of period t	Monthly
$\Delta$ PartHF	Percentage Change of participation of hedge funds	Difference between the variable PartHF in period t and period t-1	Monthly
$\Delta$ NHF	Variation in amount of hedge funds in numbers	Difference between the variable QtdHF in period t and period t-1	Monthly
MktCap	Market Cap	Napierian logarithm (ln) of stock price at the end of period i multiplied by the number of stocks in the company at the same period	Monthly
BTM	Book-to-Market	Ratio between PT and market value of company i in period t	Monthly
Beta	Beta	Ratio between covariance of market return of company i in period t and the market return by the variance of market return	Monthly
ROE	Return on Equity	Ratio between the net profit of company i in period t by the equity account of period t-1	Quarterly
Debt	Leverage	Ratio of total demandable by equity account of company i in period t	Quarterly
Liq	General Liquidity	Ratio between total asset and liability of company i in period t	Quarterly
LiqMkt	Market Liquidity	Ratio between medium negotiated volume and market value of company i in period t	Monthly
EHF	Entry Dummy	Equal to 1 for company i that had hedge fund output in period t and 0, if otherwise	Monthly
SHF	Output Dummy	Equal to 1 for company i that had hedge fund output in period t and 0, if otherwise	Monthly

We used Campbell, Lo and MacKinlay (1997) to calculate the abnormal return and the CAPM model to estimate the predicted return.

$$E(R)_{it} = \beta(Rm_{it} - Rf_{it}) + Embi_t + \varepsilon_{it} \quad (4)$$

where

$E(R)_{it}$  = expected return rate of stock  $i$  in period  $t$

$Rm_{it}$  = Monthly return of American Market measured by the variation in index points of S&P.

$Rf_{it}$  = Monthly return of fixed income titles of American market ( $t$ -bond of 10 years).

$Embi_t$  = Monthly average country risk measure denominated EMBI+

The abnormal return  $RA_{it}$  was calculated by the difference between the expected return  $E(R)_{it}$  estimated by CAPM model and the effective stock return.

## 4 RESULTS AND SAMPLE CHARACTERISTICS

### 4.1 Descriptive Statistics

Table 5 brings the descriptive statistics of variables in in model. All variables were winsorized at 2.5%. The sample Book-to-Market median is smaller than one, supporting the common argument that hedge funds acquire participations in undervalued companies. The

abnormal return (RA) and the change variables ( $\Delta$ PartHF and  $\Delta$ NHF) have negative average values, while the stock effective return (RE) presents, on average, positive values. The firms' market value (MktCap) owns a more symmetrical distribution. Regarding the market liquidity (LiqMkt), the median is near the first quartile and relatively lower than the average rate, indicating that companies that are in the third and fourth quartile have a high liquidity in the stock market, while the biggest part of listed companies have low liquidity.

Table 5  
**Descriptive Statistics of Variables**

This table presents the descriptive statistics of variables used in models detailed in equations 1, 2 and 3, the number of observations and the measures of position and dispersion, with information of companies listed in São Paulo Stock Market (B3) that have or do not have participation in hedge funds from 2007 to 2016.

Variable	Obs.	Mean	SD	Median	Min.	Q1	Q3	Max.
PartHF	27300	0.00	0.02	0.00	0.00	0.00	0.00	0.88

PartHF - how much in percentual terms of market value in company,  $i$ , listed in São Paulo Stock Market (B3) in a period  $t$  is detained by *hedge funds*; NHF quantity of funds that invest in a company  $i$  at the end of period  $t$ ;  $\Delta$ PartHF - difference between the variable PartHF in period  $t$  and period  $t-1$ ;  $\Delta$ NHF - difference between the variable NHF in period  $t$  and period  $t-1$ ; EHF - dummy entry variable - equal to 1 for company  $i$  in period  $t$  that owns *hedge fund* and 0, if otherwise; SHF - dummy output variable - equal to 1 for company  $i$  in period  $t$  that does not have a hedge fund participation and 0, if otherwise; RE - effective return of stock calculated by the ratio between stock price in period  $t$  and the stock price in period  $t-1$ ; RA - abnormal return calculated by the different between stock returns of company  $i$  in period  $t$  and the expected return (equation 4); MktCap - Napierian logarithm ( $\ln$ ) of price of final stock in period  $i$  multiplied by the number of stocks in the company at the same period; Book-to-Market - ratio between the PL and market value of company  $i$  in period  $t$ ; Vol - standard deviation of return of company  $i$  in period  $t$ ; Beta - ratio between the covariance of return of company  $i$  in period  $t$  and the market return by variance of market return; ROE - ratio between the net profit of company  $i$  in period  $t$  by the equity of period  $t-1$ ; Debt - ratio of total demandable by the equity of company  $i$  in period  $t$ ; Liq - General liquidity index - ratio between the asset and liability of company  $i$  in period  $t$ ; LiqMkt - ratio between the medium negotiated volume and market value of company  $i$  in period  $t$ .

Source: Resource data adapted by the author himself

Table 6 presents mean comparison group tests. We compare firms with participation of hedge funds to companies with no hedge funds participation. The variables RE and abnormal return RA have no significant mean difference, what signals that, on average, there are no statistically differences between effective and abnormal return between companies that own hedge funds participations and companies that do not.

Table 6  
**Mean Tests**

The table below presents the difference of means test between month-companies listed in São Paulo Stock Market (B3) with participation of hedge funds in any month of the year versus month-companies also listed in B3 with no participation of hedge funds during the year. The objective is analyzing if there is any initial

significate differences between groups with and without hedge funds participation. For that, the dependent variables of models presented in equations 1, 2 and 3 (RA, RE and Vol) and control variables were compared between 2007 and 2016.

Variable	With HF participation		Without HF participation		Average Difference	P-Value
	Mean	SD	Mean	SD

In terms of stock volatility groups (Vol), there are statistically significant differences with trust level of 99%. This result indicates that, on average, the hedge funds seek for companies with more profitabiliy and liquidity in stocks that follow the market variation (beta), following Bessler, Drobetz and Holler (2015).

## 4.2 Results

To derive our results, we used panel with funds fixed effects model. Table 7 presents the regression of Equation 1, using the abnormal return as dependent variable. We split the stocks in ordinary (ON), preferential (PN) and other classes. For each class, it is presented the coefficient and the p-value ( $P > |t|$ ) of regression.

The results of these estimates indicate that the explanatory variables participation and quantity of hedge funds, in most cases, affect negatively the abnormal return of companies. However, the effect is positive when the analysis is based on variables that measure the variation of participation and quantity of hedge funds. This is evidence that the raise of participation or quantity of funds generates value for the company and, consequently, a raise of abnormal return. As it is presented in literature (Clifford, 2008; Brav et al., 2008; Greenwood & Schor, 2009; Gantchev, 2013; Bebchuk, Brav & Jiang, 2015), it was expected that these two variables had a positive impact in return.

The variable of control related to profitability (ROE) also presented positive and significate signs of 99% of trustworthiness for ordinary and preferential classes, and 95% of trustworthiness for the classes left. The variable Market Cap presents a positive and significate sign for stocks ON and PN, following Clifford (2008), Bessler, Drobetz and Holler (2015) and Becht et al. (2017), indicating that companies that have good indexes of profitability present for their shareholders good results/returns. In the same way, companies that own market values higher than accounting values also generate positive returns.

Our results are aligned to Clifford (2008), Brav et al., (2008), Bessler, Drobetz and Holler (2015) and Becht et al., (2017), indicating that the acting of hedge funds affects the

return of target companies, by the participation or by the number of funds invested in the stock market.

## 5 FINAL REMARKS

This research brought evidence that the equity stake of hedge funds generates value for target companies in less sprayed markets like Brazil. The contribution of this research is related to academic and practical discussion of the theme exposed, not only under the view of value generating for shareholders associated to the hedge funds, but also in the sense of understanding the relation between the equity stake of this segment and the price rise of target companies. Our results endorse researches of Clifford (2008), Bessler, Drobetz and Holler (2015) and Becht et al., (2017), and confirm a positive and significant relation between investment funds and value generation for target companies.
